JW77216

60V, 10mΩ Synchronous Rectifier

Preliminary Specifications Subject to Change without Notice

DESCRIPTION

JW®77216 is a synchronous rectifier, used for the secondary side rectification of isolation topologies, such as Active Clamp Flyback and CCM/QR/DCM Flyback. JW77216 is able to significantly improve the efficiency comparing with the conventional Diode rectifier.

When JW77216 senses V_{ds} of MOSFET less than -140mV, it turns on the internal MOSFET. Once the V_{ds} is greater than -3mV, JW77216 turns off the internal MOSFET.

JW77216 supports multiple operation modes, such as DCM, CrCM, CCM and Quasi-Resonant. By implementing the Joulwatt proprietary technology, JW77216 is able to handle CCM operation.

JW77216 is available in SOP-8 package.

FUNCTIONAL DESCRIPTION

Operation

JW77216 is a synchronous rectifier combined with internal MOSFET can replace the Schottky Barrier Diode. It supports all operations, such as DCM, CrCM, (Quasi-Resonant) and CCM when adopted in Active Clamp Flyback and Flyback converters.

Startup

During the startup period, when the VCC is charged up by the two internal LDOs connected to SW and VO pin respectively.

A capacitor between VCC and GND is required to store the energy and supply to IC during the SR turn-on period.

Once the VCC voltage exceeds $V_{CC\_Startup}$, the JW77216 exits the UVLO. If VCC is lower than V_{CC_UVLO} ($V_{CC\_Startup}$-0.5V), the internal MOSFET is turned off. The current flows though body diode before the VCC reaches to the startup voltage $V_{cc\_startup}$.

Under-Voltage Lockout (UVLO)

When the VCC is below UVLO($V_{CC\_Startup}$-0.5V) threshold, the internal MOSFET is turned off and pulled low internally. Once the VCC exceeds the startup voltage Vcc_startup, the parts is activated again.

Turn On Phase

There are two conditions for the JW77216 to turn on the internal MOSFET, i.e. Vsw, voltage-second value on SW pin when primary side switch is on, and the turn on phase is shown in Figure. 1.

1) Vsw: when the synchronous MOEFET is conducting, current flows through the body diode of MOSFET, which generates a negative voltage V_{SW} across it. When V_{SW} is lower than V_{MOS_ON}, the part will pull the gate high to turn on the synchronous MOSFET after turn on delay time T_{DON} if the other condition is met.

2) Volt-second of SW: in DCM and QR operation, there are parasitic oscillations. In some applications, the drain resonant voltage may fall below the SR turn on threshold, especially for the first couple rings. SR could be falsely turned on, which may cause shoot through issue and result in high power loss. The volt-second value of SW pin can be used to distinguish the parasitic ring from normal primary side switch on. The threshold can be set by the resistance at VT pin. The curve is shown in Figure. 2.

Minimum On Time (MOT)

When the synchronous MOSFET is turn on, there is a minimum on time for the SR. The V_{SW} voltage may have a parasitic ring when the synchronous MOSFET turns on. So, a minimum on time (MOT) is very important to avoid the MOSFET turn off threshold is false triggered. Minimum on time is about 1.1us.

Conducting Phase

When the synchronous MOSFET is turned on, the drain source voltage V_{SW} it is determined by its on resistance and the current through it. The part adjusts the gate voltage and regulates the Vsw to the internal threshold (typical -40mV) after the synchronous MOSFET turn on. When the V_{SW} is lower than -40mV, the gate keeps its maximum voltage. And the synchronous MOSFET is fully on.

The V_{SW} rises when the current follow through the MOSFET decreases. The gate voltage will be decreased to increase its on resistance and regulate the V_{SW} around -40mV.

It should be noted that the typical regulation threshold (typical -40mV) during MOSFET on time is not fixed, it can be internally changed to ensure the proper operation under CCM mode.

Turn Off Phase

After synchronous MOSFET conducting, once the voltage V_{SW} touches the MOSFET turn off threshold, the gate is pulled to low after a turn off delay time T_{DOFF}. A 365nS blanking time is necessary to avoid error trigger. The banking time is reset once Vsw rises above +2.5V.
